

SAKATA LETTUCE ENHANCEMENT

Pelleted Seed – What Are The Benefits?

Pelleting seed increases the efficiency of sowing and provides the seed protection from the elements. In addition, the practice of pelleting seed optimizes oxygen and moisture absorption, increasing your chances of germination and ultimately, growing ease and success!

At Sakata, we work closely with a network of credible and dependable seed coating companies to ensure our seed has the highest probability for success in the full spectrum of production conditions.

Sakata lettuce customers have many convenient choices – **raw seed is available primed or non-primed; pellets are available in conventional or organic, primed or non-primed.**

When it comes to pelleting, density matters...

Sakata is here to help, and suggests different pellet densities to meet growers needs to “fine-tune” planting to varied soil and weather conditions.

Lighter pellets weigh less per unit volume (boxes and pails are packed by seed number), so shipping costs are lower and handling is easier. Generally, light pellets are preferred by indoor growers using a vacuum planter.

Heavy or high-density pellets are used for precise seed placement in heavier soils. Pellet weight is a factor when considering certain soil conditions and tractor/planter speed, and are the best choice for warmer production areas – such as the desert or other extreme weather locations.

Medium pellets fall somewhere in between light and heavy coatings, and are more of a universal option intended for moderate climates or to be used interchangeably depending on grower preference in either the coastal or desert regions.

- Special treatments, including Thiram and Nipsit, are available to be added upon request.
- For a full list of options available, please contact the Sakata Seed America Lettuce Team at vegetables@sakata.com.

WHAT IS PRIMING? Priming is a process used to control the uptake of water by seed thereby starting the germination process.

WHY PRIME? Priming is used to increase the uniformity of emergence and to help alleviate thermodormancy (heat-induced seed dormancy) and photodormancy (seed dormancy in the absence of light).
